## IN THE CLAIMS:

 (Previously Amended) A device for manipulating a molecule in vivo relative to a target tissue comprising:

an elongated member comprising a generally cylindrical nonconductive core post and at least three discrete electrodes;

the least three discrete electrodes being circumferential rings disposed about the core and in axially spaced relation along the elongated member, each electrode being in independent circuit communication with a respective portion of a source of electrical energy, the discrete electrodes being configured to establish a first electromagnetic field *in vivo* between selected electrodes sufficient to cause an electromigration of a molecule relative to a target tissue and a second electromagnetic field sufficient to cause transient permeability of a cell membrane within the target tissue; and

an insulating material interposed axially between the electrodes for achieving relative electromagnetic isolation of the electrodes.

- 2. (Previously Amended) The device recited in Claim 1, wherein the second field is higher in strength than the first field.
- 3. (Original) The device recited in Claim 1, wherein the elongated member is geometrically adapted for insertion into the target tissue.
- 4. (Previously Amended) The device recited in Claim 1, wherein the core has a tip positioned at a distal end of the core post.
- 5. (Original)The device recited in Claim 1, wherein the member comprises a plurality of members configurable to surround a periphery of at least a portion of the target tissue.
- 6. (Original) The device recited in Claim 1, wherein the member comprises a pair of members configured in spaced-apart relation and adapted to provide at least one pair of opposite-polarity voltages approximately simultaneously on at least one electrode on each member.

- 7. (Original) The device recited in Claim 1, further comprising means for selectively activating a selected plurality of electrodes in a predetermined pattern.
- 8. (Original) The device recited in Claim 1, wherein the electrodes are substantially simultaneously activatable.
- 9. (Original) The device recited in Claim 1, wherein the member has a lumen therethrough extending from an opening adjacent a top of the member to a portal positioned along the member beneath the top opening for passing a substance therethrough to the target tissue.
- 10. (Previously Amended) The device recited in Claim 9, wherein the portal is positioned adjacent a bottom tip of the member.
- 11. (Previously Amended) The device recited in Claim 9, wherein the portal is positioned along the member adjacent an electrode.
- 12. (Previously Amended) A device for manipulating a molecule *in vivo* relative to a target tissue comprising:

an elongated member comprising a generally cylindrical nonconductive core post and at least three discrete electrodes;

the least three discrete electrodes being circumferential rings disposed about the core and in axially spaced relation along the elongated member, each electrode being in independent circuit communication with a respective portion of a source of electrical energy, the discrete electrodes being configured to establish a first electromagnetic field *in vivo* between selected electrodes sufficient to cause at least one of an electromigration of a molecule relative to a target tissue and transient permeability of a cell membrane within the target tissue; and

an insulating material interposed axially between the electrodes for achieving relative electromagnetic isolation of the electrodes.
